1 COPYRIGHT © D-WAVE

# LEAP™: THE REAL-TIME QUANTUM CLOUD SERVICE

#### **BUILT FOR IN-PRODUCTION APPLICATIONS**

#### **ADVANTAGE ACCESS TODAY:**

• Businesses, developers, and new users have access to the most connected and powerful quantum computer built for business

#### **SEAMLESS TRANSITION:**

- Ocean<sup>™</sup> tools use Advantage out of the box
- Existing programs will switch over with feature-based solver selection
- Hybrid solvers are adapted to the new technology and will continue improving with ongoing algorithm development

# SOFTWARE DEVELOPMENT KIT

SUITE OF OPEN-SOURCE PYTHON TOOLS ON THE D-WAVE GITHUB REPOSITORY

# BUILDING QUANTUN APPLICATIONS

## **DISTRIBUTED COMPUTING**

**GOAL:** Efficiently assign tasks to computers in a distributed environment

#### **CHALLENGES:**

- Some tasks are related and require information passing
- Each computer is assigned the same number of tasks

#### This is a challenging, NP-hard problem.

#### 6 COPYRIGHT © D-WAVE

# DISTRIBUTED COMPUTING

We have a network of computers and a set of operations to be performed.

- The operations will be distributed across the computers
- The computers will need to pass messages to share inputs/outputs

How can we minimize the message passing that's required, and evenly balance the workload?

## **GRAPH MODEL**

# **GRAPH MODEL**

#### **Graph:**

- Nodes: operations
- Edges: message needs to be passed

#### Goal:

- Partition into k sets of nodes
- k = number of computers
- Partitions should be equal size
- Minimize number of edges between partitions

#### This is known as the graph k-partitioning problem.

# **GRAPH MODEL POLL**

#### **Questions:**

Why would having very different sized partitions be inefficient?

 (a) Many more messages are passed between computers
 (b) Memory access increases significantly across all computers
 (c) Some computers have to complete many more tasks

2. What would happen if we maximized the number of edges between partitions?

(a) The system would overheat

(b) Inefficient ordering of tasks per computer

(c) Computers would have to wait for transmitted messages before finishing tasks

# DEMO

# EXAMPLE INPUT / OUTPUT

# **PROBLEM FORMULATION**

#### Input:

- Graph of nodes (operations) and edges (messages)
- k: number of partitions (computers)

#### **Objective:**

Minimize the number of edges between partitions

#### **Constraints:**

- Partitions are equal sizes
- Each node is assigned to one partition

## VARIABLES

We will use binary variables for this problem.

$$v_{i,p} = \begin{cases} 1, & \text{if node } i \text{ is in partition } p; \\ 0, & \text{otherwise.} \end{cases}$$

- Binary variables instead of integer allow us to build a constraint that the partitions have equal sizes.
- This is a standard method of encoding discrete variables using a set of binary variables

## CONSTRAINTS

- Each computer should have an equal number of tasks
- Each operation should be assigned to one computer

# CONSTRAINTS

#### **Constraints:**

• Partitions are equal sizes

$$\sum_{e \in G} v_{i,p} = \frac{|G|}{k}, \quad \text{for each partition } p$$

• Each node is assigned to one partition

$$\sum_{p \in [k]} v_{i,p} = 1, \qquad \text{for each node } i$$

#### **Objective Requirements:**

- Minimization expression
- Linear and quadratic terms

#### **General Form:**

$$Obj(a_i, b_{ij}; q_i) = \sum_i a_i q_i + \sum_{i < j} b_{ij} q_i q_j$$

## **GRAPH MODEL**

## **GRAPH MODEL**

Operation i	Operation j	
Orange	Orange	GOOD
Orange	Not Orange	BAD
Not Orange	Orange	BAD
Not Orange	Not Orange	GOOD

# $v_{i,p}$ $v_{j,p}$ 11GOOD10BAD01BAD00GOOD

# $v_{i,p}$ $v_{j,p}$ Value110101011000

We need our values to fit the general form:

 $a_i v_i + a_j v_j + b_{i,j} v_i v_j + C$ 

$v_i$	$v_j$	Value	Equation	
0	0	0	$\frac{a_i \cdot 0 + a_j \cdot 0 + b_{i,j} \cdot 0 \cdot 0 + C}{2}$	0 = c
0	1	1	$-a_i \cdot 0 + a_j \cdot 1 + b_{i,j} \cdot 0 \cdot 1 + C$	$-1 = a_j + C \longrightarrow 1 = a_j$
1	0	1	$-a_i \cdot 1 + a_j \cdot 0 + b_{i,j} \cdot 1 \cdot 0 + C$	$-1 = a_i + C \longrightarrow 1 = a_i$
1	1	0	$-a_i \cdot 1 + a_j \cdot 1 + b_{i,j} \cdot 1 \cdot 1 + C$	

For one pair of operations and one computer:

 $\min(v_{i,p} + v_{j,p} - 2v_{i,p}v_{j,p})$ 

0

4

3

8

2

For all pairs:

$$\min \sum_{(i,j)\in E} \sum_{p\in [k]} (v_{i,p} + v_{j,p} - 2v_{i,p}v_{j,p})$$

We only look at the pairs with a message (edge).

7

6

9

5

# **PROBLEM FORMULATION**

#### Input:

- Graph of nodes (operations) and edges (messages)
- k: number of partitions (computers)

# **Objective:** $\min \sum_{(i,j)\in E} \sum_{p\in[k]} (v_{i,p} + v_{j,p} - 2v_{i,p}v_{j,p})$

#### **Constraints:**

- Partitions are equal sizes:
- Each node is assigned to one partition:

 $\sum_{i \in G} v_{i,p} = \frac{|G|}{k}, \text{ for each partition } p$  $\sum_{p \in [k]} v_{i,p} = 1, \text{ for each node } i$

# **POWERFUL HYBRID SOLVERS**

#### **CONSTRAINED QUADRATIC MODEL SOLVER**

- More native representation of problem
- Unlocks larger application problems
- Inequality and equality constraints
- Hard and weighted constraints
- Binary, integer, and real/continuous variables

#### **BINARY QUADRATIC MODEL SOLVER**

- Up to 1,000,000 variables
- Enables enterprise-scale problem solving
- Accepts problems with binary variables

#### **Defining variables:**

25	<pre>from dimod import Binary, ConstrainedQuadraticModel, quicksum</pre>
115	# Cot up the partitions
112	
116	partitions = range(k)
122	# Add binary variables, one for each node and each partition in the graph
.23	<pre>print("\nAdding variables")</pre>
124	<pre>v = [[Binary(f'v {i},{p}') for p in partitions] for i in G.nodes]</pre>

#### Setting up a model:

25 from dimod import Binary, ConstrainedQuadraticModel, quicksum

119	<pre>print("\nBuilding constrained quadratic model")</pre>
119	<pre>print("\nBuilding constrained quadratic model")</pre>
118	<pre># Initialize the CQM object</pre>

#### **Defining objective function:**

138	# Objective: minimize edges between partitions
139	<pre>print("\nAdding objective")</pre>
140	<pre>min_edges = []</pre>
141	for i,j in G.edges:
142	for p in partitions:
143	<pre>min_edges.append(v[i][p]+v[j][p]-2*v[i][p]*v[j][p])</pre>
144	<pre>cqm.set_objective(sum(min_edges))</pre>

#### **Objective:**

$$\min \sum_{(i,j)\in E} \sum_{p\in [k]} (v_{i,p} + v_{j,p} - 2v_{i,p}v_{j,p})$$

#### **Defining assignment constraint:**

126	# One-hot constraint: each node is assigned to exactly one partitio
127	<pre>print("\nAdding one-hot constraints")</pre>
128	for i in G.nodes:
129	<pre># print("\nAdding one-hot for node", i)</pre>
130	<pre>cqm.add_discrete([f'v_{i},{p}' for p in partitions],</pre>
131	label=f"one-hot-node-{i}")

#### **Constraint:**

Each node is assigned to one partition:

$$\sum_{p \in [k]} v_{i,p} = 1$$
, for each node *i*

#### **Defining partition constraint:**

25 from dimod import Binary, ConstrainedQuadraticModel, quicksum

133	# Constraint: Partitions have equal size
134	<pre>print("\nAdding partition size constraint")</pre>
135	for p in partitions:
136	<pre># print("\nAdding partition size constraint for partition", p)</pre>
137	<pre>cqm.add_constraint(quicksum(v[i][p] for i in G.nodes) == G.number_of_nodes()/k,</pre>
138	<pre>label=f'partition-size-{p}')</pre>

#### **Constraint:** Partitions are equal sizes:

$$\sum_{i \in G} v_{i,p} = \frac{|G|}{k}$$
, for each partition  $p$ 

#### **Connecting to D-Wave hybrid solver:**

26 <b>fro</b>	m dwave.	system	import	LeapHybr	idCQMSampler
---------------	----------	--------	--------	----------	--------------

293	<pre># Initialize the CQM solver</pre>
294	<pre>print("\n0ptimizing on LeapHybridCQMSampler</pre>
005	

11

295 sampler = LeapHybridCQMSampler()

#### Sampling the problem:

163	# S	olve the	e CQM pro	oblem us	ing the	solver				
164	sam	pleset =	sample:	r.sample	_cqm(cqm	, label=	'Example – G	raph Part	itioning'	)
	v_0,0	v_0,1	v_0,2	v_0,3	v_1,0	v_1,1 \	v_1,2	v_99,3	energy	num_oc.
0	0.0	0.0	0.0	1.0	0.0	0.0	0.0	0.0	6.0	1
1	0.0	0.0	1.0	0.0	0.0	0.0	1.0	0.0	6.0	1
2	0.0	0.0	0.0	1.0	0.0	0.0	0.0	0.0	6.0	1
3	0.0	0.0	0.0	1.0	0.0	0.0	0.0	0.0	6.0	1
4	0.0	0.0	1.0	0.0	0.0	0.0	1.0	0.0	6.0	1

#### **Interpret results:**

<pre>166 feasible_sampleset = sampleset.filter(lambda row: row.is_feasible) 167 168 # Return the first feasible solution 169 if not len(feasible_sampleset): 170 print("\nNo feasible solution found.\n") 171 return None 189 189 partitions = defaultdict(list) 190 soln = [-1]*G.number_of_nodes() 191 192 for node in G.nodes: 193 for p in range(k): 194 if sample[f'v_{node},{p}'] == 1:</pre>

# DEMO

# **D-WAVE SOLVERS**

#### **Hybrid Solvers:**

- Combines classical optimization and quantum annealing
- Supports binary, discrete, integer, and continuous variables
- ConstrainedQuadraticModel

#### Pure Quantum Solver:

- Only uses quantum annealing
- Supports binary or Ising variables
- Quadratic Unconstrained Binary Optimization (QUBO)

# **PROBLEM FORMULATION**

#### Input:

- Graph of nodes (operations) and edges (messages)
- k: number of partitions (computers)

# **Objective:** $\min \sum_{(i,j)\in E} \sum_{p\in[k]} (v_{i,p} + v_{j,p} - 2v_{i,p}v_{j,p})$

#### **Constraints:**

- Partitions are equal sizes:
- Each node is assigned to one partition:

 $\sum_{i \in G} v_{i,p} = \frac{|G|}{k}, \text{ for each partition } p$  $\sum_{p \in [k]} v_{i,p} = 1, \text{ for each node } i$ 

# PROBLEM FORMULATION POLL

#### Questions:

- 1. For only two computers, how can we reduce the number of variables in our problem?
  - (a) By saying computers can't talk to each other
  - (b) By changing each variable to represent a binary assignment between the two computers
  - (c) By assigning some tasks to one computer by hand

- 2. If we change each variable to represent a binary assignment, which constraint is no longer necessary?
  - (a) Partitions are equal size
  - (b) Each node is assigned to one partition
  - (c) Both are unnecessary

# **PROBLEM FORMULATION**

#### Input:

- Graph of nodes (operations) and edges (messages)
- k=2: number of partitions (computers)

# **Objective:** $\min \sum_{(i,j)\in E} (v_i + v_j - 2v_i v_j)$

#### **Constraints:**

• Partitions are equal sizes:

$$\sum_{i\in G} v_i = \frac{|G|}{2}$$

Each node is assigned to one partition:

# **PROBLEM FORMULATION**

#### **Combine objective and constraints:**

$$\min \sum_{(i,j)\in E} (v_i + v_j - 2v_i v_j) + \gamma \left(\sum_{i\in G} v_i - \frac{|G|}{2}\right)$$

$$\min \sum_{(i,j)\in E} (v_i + v_j - 2v_i v_j) + \gamma \sum_{i\in G} v_i^2 + \gamma \sum_{i\in G} \sum_{j>i} 2v_i v_j - \gamma |G| \sum_{i\in G} v_i + \gamma \frac{|G|}{4}$$

#### Simplify:

$$\min \sum_{(i,j)\in E} (v_i + v_j - 2v_i v_j) + 2\gamma \sum_{i\in G} \sum_{j>i} v_i v_j + (1 - |G|)\gamma \sum_{i\in G} v_i v_j$$

# **QUBO FORMULATION**

#### Input:

- Graph of nodes (operations) and edges (messages)
- k=2: number of partitions (computers)

#### **Objective:**

$$\min \sum_{(i,j)\in E} (v_i + v_j - 2v_i v_j) + 2\gamma \sum_{i\in G} \sum_{j>i} v_i v_j + (1 - |G|)\gamma \sum_{i\in G} v_i$$

#### Steps to solving a QUBO problem with D-Wave's technology:

- 1. Build QUBO dictionary
- 2. Connect to D-Wave sampler
- 3. Sample problem using the solver
- 4. Interpret results

May need embedding!

#### Set parameters!
